ABSTRACT

Specific heat and speed of sound data have been computed for imperfect air. The thermodynamic data included the effects of two-body intermolecular forces, and the results were obtained by numerical interpolation and differentiation of the recent data of Hilsenrath and Klein (AEDC-TDR-63-161). Comparisons with previous perfect gas calculations showed small effects in the isentropic exponent γ_E and dimensionless speed of sound a/a_a below one amagat and negligible effects on the specific heat data for all densities up to $\log \rho = 2.2$.

PUBLICATION REVIEW

This report has been reviewed and publication is approved.

NOMENCLATURE

a	Speed of sound, ft/sec
C_p/R	Dimensionless specific heat at constant pressure
C_v/R	Dimensionless specific heat at constant volume
E/RT	Dimensionless internal energy
H/RT	Dimensionless enthalpy
p	Pressure, atm
R	Gas constant
S/R	Dimensionless entropy
T	Temperature, °K
Z	Compressibility factor, $p/\rho RT$
γ	Ratio of specific heats, C_p/C_v
γ_E	Isentropic exponent, $(\partial \log p / \partial \log \rho)_S$
ρ	Density, amagats
\log	All logarithms are to the base 10

1.0 INTRODUCTION

For gas dynamic calculations at high temperature, gas properties are needed which take proper account of so-called real gas effects. Equilibrium gas properties for a perfect gas* mixture have been computed by numerous investigators in recent years (e.g., Refs. 1 through 7).

The National Bureau of Standards under delivery orders to the Arnold Engineering Development Center (AEDC), Air Force Systems Command (AFSC), has been a prime source of data for the thermodynamic properties of gases. Perfect gas data for argon-free air were published by Hilsenrath and Beckett (Ref. 6)[†] who considered air as a 16-component mixture. Later Hilsenrath, Klein, and Woolley (Ref. 7)^{††} published perfect gas properties for a 28-component mixture. Even more recently Hilsenrath and Klein (Ref. 8)^{‡‡} included the second virial coefficient to account for the effects of intermolecular forces which become important at high densities or pressures. In all these publications, E/RT , H/RT , Z , ρ , and p were tabulated at constant temperature in the range from 1500 to 15,000°K.

Landis and Nilson (Ref. 9) computed specific heat and speed of sound data based on the 1959 air data, and some comparisons are given in Section 3.0 between their results and those of the present calculations. The procedure used for the present calculations was similar to the one used by Landis and Nilson and is described in detail in Section 2.0.

The data in tabular form require large storage areas when used in machine computations. For this reason empirical fits of the data are desirable. Grabau (Ref. 10) fitted the 1956 air data with equations for

*The following terminology will be used in this report. An ideal gas will denote a gas obeying the equations $p = \rho RT$ and $h = C_p T$. A perfect gas will denote one obeying $p = Z \rho RT$ which includes dissociation and ionization neglecting intermolecular effects. An imperfect gas obeys $p = Z \rho RT$ but includes intermolecular (two-body interaction) forces. The term real gas is reserved for a gas under actual (experimental) conditions and is not subject to the theoretical approximations.

[†]These data will subsequently be referred to as the 1956 air data.

^{††}These data will subsequently be referred to as the 1959 air data.

^{‡‡}Hereinafter called 1963 air data.

Manuscript received April 1964.

$H\rho/p$, S/R , and $1/Z$ as functions of p and ρ . Recently, Lewis and Burgess (Ref. 11) developed empirical surface fits for the 1959 air data as well as some unpublished perfect gas nitrogen data of Hilsenrath. In that work H/R , ρ , Z , and a/a_a were given as functions of p and S . The speed of sound data were computed as described below, and a comparison with the results of Landis and Nilson indicated small differences.

The speed of sound data of this report together with H/R , ρ , and Z for the 1963 air data are being fitted as functions of p and S , and these results will be published in the future by Lewis and Burgess.

2.0 CALCULATION PROCEDURE

The 1963 air data were interpolated at constant pressure in the range $\log p = -7$ (in intervals of 0.1) 4.0 and at constant entropy in the range $S/R = 23.0$ (0.2) 133.0 over the temperature range 1500 (100) 15,000°K. A four-pound Lagrange interpolation formula was used in both cases. A four-point pressure interpolated data were arranged in tables of the form $\phi = \phi(\log p; T, \log \rho, H/RT, Z, \log(E/R))^*$.

The constant entropy interpolated data were numerically differentiated using a two-point central difference formula to yield the isentropic exponent $\gamma_E = (\partial \log p / \partial \log \rho)_S$, and the speed of sound was calculated from $a = (\gamma_E ZRT)^{1/2}$. The constant entropy interpolated data were arranged in tables of the form $\phi = \phi(S/R, \log \rho, \log p, H/RT, \gamma_E, a/a_a, \log(E/R), Z)$ where the notation is similar to that used above.

The specific heat data were computed using the Landis and Nilson spline fit procedure from the original tables, i.e., $\phi = \phi(T; \log \rho, \log p, H/RT, E/RT, Z)$, and the constant pressure and entropy interpolated data as follows:

1. From the originally tabulated 1963 air data, the specific heat at constant volume was computed

$$C_v/R \equiv [\partial(E/R)/\partial T]_v = T[\partial(E/RT)/\partial T]_\rho + E/RT$$

2. From the constant pressure interpolated data, the specific heat at constant pressure was calculated

$$C_p/R \equiv [\partial(H/R)/\partial T]_p = T[\partial(H/RT)/\partial T]_\rho + H/RT$$

*This is used to denote that for a given pressure and any one of the remaining quantities, all other thermodynamic properties can be determined by interpolation.

3. These data were placed in the original format, i.e., in terms of T and ρ , and the ratio $\gamma = C_p/C_v$ was taken.
4. The isentropic exponent γ_E ($S/R; \log \rho, T, \dots$) and the speed of sound a/a_a ($S/R, \log \rho, T, \dots$) data were interpolated again at constant density and tabulated in the form $\phi = \phi(T; \log \rho, S/R, \dots)$.

3.0 RESULTS AND DISCUSSION

The specific heat and speed of sound data based on the above described calculation procedure and the data of Hilsenrath and Klein (1963 air data) are given in the table, and the data in the range $T = 2000$ (2000) $14,000^{\circ}\text{K}$ are shown in Figs. 1 through 5.

The spline fit procedure used to compute the specific heat data was tested using the 1959 air data, and the results were compared with Landis and Nilson. The choice of end restraints was the same as that used by Landis and Nilson*, and the C_v/R results agreed within five in the fourth significant figure for $T \leq 10,000^{\circ}\text{K}$.

Above $T = 10,000^{\circ}\text{K}$ and for densities below one amagat, differences were found when the present results were compared with those of Landis and Nilson. A calculation was made at $14,200^{\circ}\text{K}$ and $\log \rho = -5$ using single and double precision arithmetic. The results are shown below:

Source	Single Precision		Double Precision	
	Slope	C_v/R	Slope	C_v/R
Present Calculations				
1963 Air Data	0.0018961	9.86019	0.0018955	9.86871
1959 Air Data		8.2511		
Landis and Nilson (Ref. 9)				
1959 Air Data		8.231 [†]		

From these results the effects of arithmetic precision is much smaller than the difference between the tabulated 1963 and 1959 air data. The temperature interval above $10,400^{\circ}\text{K}$ was increased from 100 to 200°K in the 1959 air tables, whereas the interval was maintained constant at 100°K throughout the 1963 air tables. The present calculations are therefore considered more accurate above $10,000^{\circ}\text{K}$ than the previously available data.

*As noted by Landis and Nilson (Ref. 9), the choice is arbitrary.

†The arithmetic precision used by Landis and Nilson is not known.

A further possible source of error was investigated when data* computed at specific values of T and S/R were compared with the present interpolated data. The comparison showed that the present data agreed within five significant figures at 2500°K where both sets of data were available.

From these comparisons it can be stated that the significant differences between the present results and those of Landis and Nilson at high temperature and low density are caused by differences in the tabulated 1959 and 1963 air data and not in the computation method or arithmetic precision. The interested reader can find further perfect gas comparisons in Refs. 9 and 12.

The imperfect gas effects on γ_E and a/a_a at 10,000°K are shown in Fig. 6. Note here that below one amagat the differences are negligible. The comparisons for the specific heat data are not shown since the differences are, in general, less than one percent over the entire density range.

4.0 CONCLUDING REMARKS

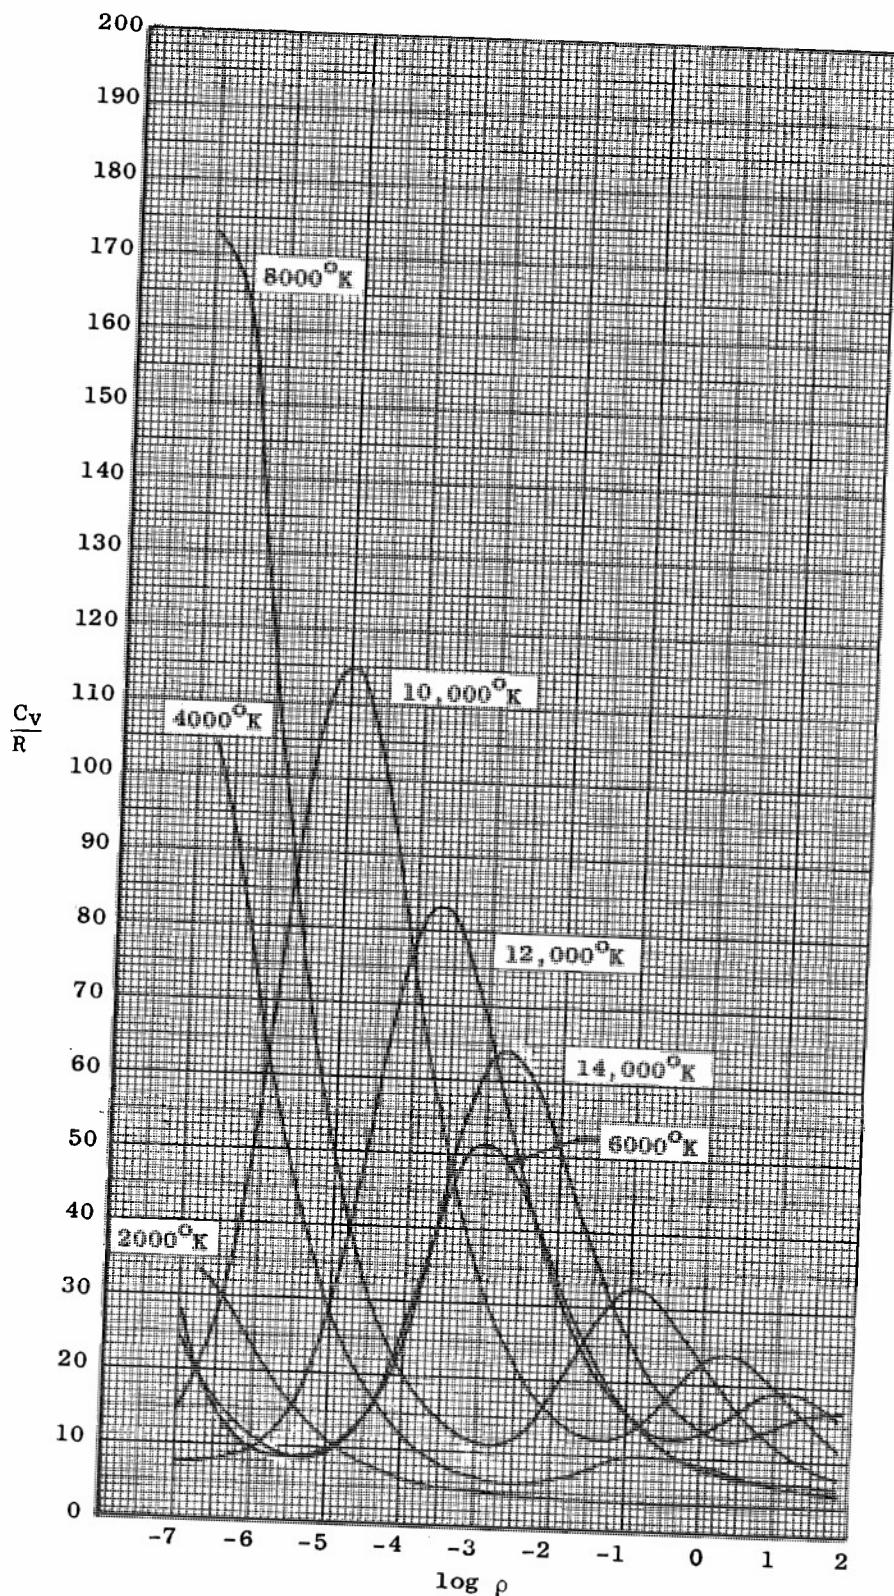

Specific heat and speed of sound data have been computed where imperfect gas effects were included in the thermodynamic data. At temperatures below 10,000°K and densities below one amagat, comparisons with previous calculations based on perfect gas properties indicate small differences, and for all densities in the same temperature range the effects on the specific heat data are small. Above 10,000°K the differences appear to be caused by the differences in the tabulated data. The present results are believed to be sufficiently accurate for most engineering calculations.
